Abstract: This paper presents a preliminary analysis of Websites contained in a large-scale web crawl of the .ng domain that was collected by the Nigerian Scientific and Industrial Research Organization (NSIRO) in late 2007. Our analysis is based on a 10 percent random sample of the NSIRO crawl dataset, which contains approximately 2 million Web pages from approximately 20,000 Websites. This paper represents the first step in a larger planned project which we title the “.ng Census”, the aim of which is to use large-scale Web crawls to conduct research into commercial and social aspects of the Nigerian public Web. The primary aim of the present paper is the analysis of the data's properties. We find that the dataset predominantly consists of commercial Websites (78 percent of sites are “.com.ng”) while .edu.ng, .org.ng and .net.ng sites each account for around 5-6 percent of all sites (and .gov.ng sites are approximately 2 percent).

Keywords: analysis, large-scale web crawl, dataset, sites, approximately
